ANTISENSE MODULATION OF FOCAL ADHESION KINASE EXPRESSION

INTRODUCTION

This application is a continuation of U.S. Application No. 09/757,100 filed January 9, 2001, which is
5   a continuation-in-part of the PCT Application No. PCT/US00/18999 filed July 13, 2000 which corresponds to U.S. Application No. 09/377,310 filed August 19, 1999 now issued U.S. Patent No. 6,133,031.

FIELD OF THE INVENTION

10   This invention relates to compositions and methods for modulating expression of the human focal adhesion kinase (FAK) gene, which encodes a signaling protein involved in growth factor response and cell migration and is implicated in disease. This invention is also directed
15   to methods for inhibiting FAK-mediated signal transduction; these methods can be used diagnostically or therapeutically. Furthermore, this invention is directed to treatment of conditions associated with expression of the human FAK gene.

20 ### BACKGROUND OF THE INVENTION

Cell migration is fundamental to a variety of biological processes and can be induced by both integrin receptor-mediated signals (haptotaxis migration) and/or soluble growth factor-mediated signals (chemotaxis
25   migration). Integrin receptor engagement activates focal adhesion kinase (FAK, also pp125FAK), a non-receptor protein-tyrosine kinase localized to cell substratum-extracellular matrix (ECM) contact sites that function as

part of a cytoskeletal-associated network of signaling proteins (Schlaepfer, D.D., *et al., Prog. Biophys. Mol. Biol.*, **1999**, *71*, 435-478). In adherent cells, FAK is often associated with integrins at focal adhesions (Schaller,

5   M.D., *et al., Proc. Natl. Acad. Sci. USA*, **1992**, *89*, 5192- 5196). Numerous other signaling proteins, including other protein tyrosine kinases are associated with FAK at these regions. Phosphorylation of FAK results in activation of the mitogen-activated protein kinase pathway. In addition,

10 FAK regulates activation of phosphatidylinositol 3'-kinase which may serve to prevent apoptosis. FAK has also been shown to be required for internalization of bacteria mediated by invasin (Alrutz, M.A. and Isberg, R.R., *Proc. Natl. Acad. Sci. USA*, **1998**, *95*, 13658-13663).

15   Normal cells typically require anchorage to the extracellular matrix in order to grow. When these cells are removed from the extracellular matrix, they undergo apoptosis. Transformed cells, on the other hand, can grow under anchorage-independent conditions, providing them a

20 growth advantage and the ability to be removed from their normal cellular environment.

         Overexpression of FAK is involved in cancer progression. High levels of FAK correlates with invasiveness and metastatic potential in colon tumors

25 (Weiner, T.M., *et al., Lancet*, **1993**, *342*, 1024-1025), breast tumors (Owens, L.V., *et al., Cancer Res.*, **1995**, *55*, 2752-2755), and oral cancers (Kornberg, L.J., *Head Neck*, **1998**, *20*, 634-639).

         FAK's role in cell migration has led to the

30 speculation that it may be relevant in other diseases such as embryonic development disfunctions and angiogenic disorders (Kornberg, L.J., *Head Neck*, **1998**, *20*, 634-639).

         There is a lack of specific inhibitors of FAK. Antisense approaches have been a means by which the

function of FAK has been investigated. Lou, J. *et al.* (*J. Orthopaedic Res.*, **1997**, *15*, 911-918) used an adenoviral based vector to express antisense FAK RNA to show that FAK is involved in wound healing in tendons. Another antisense

5 FAK expression vector containing 400 bp of complementary sequence was used to study the interaction of type I collagen and ?2?1 integrin (Takeuchi, Y., *et al., J. Biol. Chem.*, **1997**, *272*, 29309-29316).

Antisense oligonucleotides have been used in several

10 studies. Tanaka, S. *et al.* (*J. Cell. Biochem.*, **1995**, *58*, 424-435) disclose two antisense phosphorothioate oligonucleotides targeted to the start site of mouse FAK. Xu, L.-H., *et al.* (*Cell Growth Diff.*, **1996**, 7, 413-418) disclose two antisense phosphorothioate oligonucleotides

15 targeted within the coding region of human FAK. They also show that FAK antisense treatment could induce apoptosis in tumor cells. Sonoda, Y., *et al.* (*Biochem. Biophys. Res. Comm.*, **1997**, *241*, 769-774) also demonstrated a role for FAK in apoptosis using antisense phosphorothioate

20 oligonucleotides targeted to the start site and within the coding region of human FAK. Shibata, K., *et al.* (*Cancer Res.*, **1998**, *58*, 900-903) disclose antisense phosphorothioate oligonucleotides targeted to the start site and coding region of human FAK. Narase, K., *et al.*

25 (*Oncogene*, **1998**, *17*, 455-463) disclose an antisense phosphorothioate oligonucleotide targeted to the start site of human FAK.

There remains a long-felt need for improved compositions and methods for inhibiting FAK gene

30 expression.

SUMMARY OF THE INVENTION

The present invention provides antisense compounds which are targeted to nucleic acids encoding focal adhesion

kinase expression (FAK) and are capable of modulating FAK mediated signaling. The present invention also provides chimeric oligonucleotides targeted to nucleic acids encoding human FAK. The antisense compounds of the

5 invention are believed to be useful both diagnostically and therapeutically, and are believed to be particularly useful in the methods of the present invention.

The present invention also comprises methods of modulating FAK mediated signaling, in cells and tissues,

10 using the antisense compounds of the invention. Methods of inhibiting FAK expression are provided; these methods are believed to be useful both therapeutically and diagnostically. These methods are also useful as tools, for example, for detecting and determining the role of FAK

15 in various cell functions and physiological processes and conditions and for diagnosing conditions associated with expression of FAK.

The present invention also comprises methods for diagnosing and treating cancers, including those of the

20 colon, breast and mouth. These methods are believed to be useful, for example, in diagnosing FAK-associated disease progression. These methods employ the antisense compounds of the invention. These methods are believed to be useful both therapeutically, including prophylactically, and as

25 clinical research and diagnostic tools.

DETAILED DESCRIPTION OF THE INVENTION

FAK plays important roles in integrin-mediated signal transduction. Overexpression of FAK is associated with tumor progression and metastatic potential. As such, this

30 protein represents an attractive target for treatment of such diseases. In particular, modulation of the expression of FAK may be useful for the treatment of diseases such as colon cancer, breast cancer and cancer of the mouth.

The present invention employs antisense compounds, particularly oligonucleotides, for use in modulating the function of nucleic acid molecules encoding FAK, ultimately modulating the amount of FAK produced. This is

5 accomplished by providing oligonucleotides which specifically hybridize with nucleic acids, preferably mRNA, encoding FAK.

This relationship between an antisense compound such as an oligonucleotide and its complementary nucleic acid

10 target, to which it hybridizes, is commonly referred to as "antisense". "Targeting" an oligonucleotide to a chosen nucleic acid target, in the context of this invention, is a multistep process. The process usually begins with identifying a nucleic acid sequence whose function is to be

15 modulated. This may be, as examples, a cellular gene (or mRNA made from the gene) whose expression is associated with a particular disease state, or a foreign nucleic acid from an infectious agent. In the present invention, the targets are nucleic acids encoding FAK; in other words, a

20 gene encoding FAK, or mRNA expressed from the FAK gene. mRNA which encodes FAK is presently the preferred target. The targeting process also includes determination of a site or sites within the nucleic acid sequence for the antisense interaction to occur such that modulation of gene

25 expression will result.

In accordance with this invention, persons of ordinary skill in the art will understand that messenger RNA includes not only the information to encode a protein using the three letter genetic code, but also associated

30 ribonucleotides which form a region known to such persons as the 5'-untranslated region, the 3'-untranslated region, the 5' cap region and intron/exon junction ribonucleotides. Thus, oligonucleotides may be formulated in accordance with this invention which are targeted wholly or in part to

35 these associated ribonucleotides as well as to the

informational ribonucleotides. The oligonucleotide may therefore be specifically hybridizable with a transcription initiation site region, a translation initiation codon region, a 5' cap region, an intron/exon junction, coding

5   sequences, a translation termination codon region or sequences in the 5'- or 3'-untranslated region. Since, as is known in the art, the translation initiation codon is typically 5'-AUG (in transcribed mRNA molecules; 5'-ATG in the corresponding DNA molecule), the translation initiation

10   codon is also referred to as the "AUG codon," the "start codon" or the "AUG start codon." A minority of genes have a translation initiation codon having the RNA sequence 5'-GUG, 5'-UUG or 5'-CUG, and 5'-AUA, 5'-ACG and 5'-CUG have been shown to function *in vivo*. Thus, the terms

15   "translation initiation codon" and "start codon" can encompass many codon sequences, even though the initiator amino acid in each instance is typically methionine (in eukaryotes) or formylmethionine (prokaryotes). It is also known in the art that eukaryotic and prokaryotic genes may

20   have two or more alternative start codons, any one of which may be preferentially utilized for translation initiation in a particular cell type or tissue, or under a particular set of conditions. In the context of the invention, "start codon" and "translation initiation codon" refer to the

25   codon or codons that are used *in vivo* to initiate translation of an mRNA molecule transcribed from a gene encoding FAK, regardless of the sequence(s) of such codons. It is also known in the art that a translation termination codon (or "stop codon") of a gene may have one of three

30   sequences, i.e., 5'-UAA, 5'-UAG and 5'-UGA (the corresponding DNA sequences are 5'-TAA, 5'-TAG and 5'-TGA, respectively). The terms "start codon region," "AUG region" and "translation initiation codon region" refer to a portion of such an mRNA or gene that encompasses from

35   about 25 to about 50 contiguous nucleotides in either

direction (i.e., 5' or 3') from a translation initiation
codon. This region is a preferred target region.
Similarly, the terms "stop codon region" and "translation
termination codon region" refer to a portion of such an

5 mRNA or gene that encompasses from about 25 to about 50
contiguous nucleotides in either direction (i.e., 5' or 3')
from a translation termination codon. This region is a
preferred target region. The open reading frame (ORF) or
"coding region," which is known in the art to refer to the

10 region between the translation initiation codon and the
translation termination codon, is also a region which may
be targeted effectively. Other preferred target regions
include the 5' untranslated region (5'UTR), known in the
art to refer to the portion of an mRNA in the 5' direction

15 from the translation initiation codon, and thus including
nucleotides between the 5' cap site and the translation
initiation codon of an mRNA or corresponding nucleotides on
the gene and the 3' untranslated region (3'UTR), known in
the art to refer to the portion of an mRNA in the 3'

20 direction from the translation termination codon, and thus
including nucleotides between the translation termination
codon and 3' end of an mRNA or corresponding nucleotides on
the gene. The 5' cap of an mRNA comprises an N7-methylated
guanosine residue joined to the 5'-most residue of the mRNA

25 via a 5'-5' triphosphate linkage. The 5' cap region of an
mRNA is considered to include the 5' cap structure itself
as well as the first 50 nucleotides adjacent to the cap.
The 5' cap region may also be a preferred target region.
    Although some eukaryotic mRNA transcripts are

30 directly translated, many contain one or more regions,
known as "introns", which are excised from a pre-mRNA
transcript to yield one or more mature mRNA. The remaining
(and therefore translated) regions are known as "exons" and
are spliced together to form a continuous mRNA sequence.

35 mRNA splice sites, i.e., exon-exon or intron-exon

junctions, may also be preferred target regions, and are
particularly useful in situations where aberrant splicing
is implicated in disease, or where an overproduction of a
particular mRNA splice product is implicated in disease.

5 Aberrant fusion junctions due to rearrangements or
deletions are also preferred targets. Targeting particular
exons in alternatively spliced mRNAs may also be preferred.
It has also been found that introns can also be effective,
and therefore preferred, target regions for antisense

10 compounds targeted, for example, to DNA or pre-mRNA.

   Once the target site or sites have been identified,
oligonucleotides are chosen which are sufficiently
complementary to the target, i.e., hybridize sufficiently
well and with sufficient specificity, to give the desired

15 modulation.

   "Hybridization", in the context of this invention,
means hydrogen bonding, also known as Watson-Crick base
pairing, between complementary bases, usually on opposite
nucleic acid strands or two regions of a nucleic acid

20 strand. Guanine and cytosine are examples of complementary
bases which are known to form three hydrogen bonds between
them. Adenine and thymine are examples of complementary
bases which form two hydrogen bonds between them.

   "Specifically hybridizable" and "complementary" are

25 terms which are used to indicate a sufficient degree of
complementarity such that stable and specific binding
occurs between the DNA or RNA target and the
oligonucleotide.

   It is understood that an oligonucleotide need not be

30 100% complementary to its target nucleic acid sequence to
be specifically hybridizable. An oligonucleotide is
specifically hybridizable when binding of the
oligonucleotide to the target interferes with the normal
function of the target molecule to cause a loss of utility,

35 and there is a sufficient degree of complementarity to

avoid non-specific binding of the oligonucleotide to non-
target sequences under conditions in which specific binding
is desired, i.e., under physiological conditions in the
case of *in vivo* assays or therapeutic treatment or, in the
5   case of *in vitro* assays, under conditions in which the
assays are conducted.

Hybridization of antisense oligonucleotides with mRNA
interferes with one or more of the normal functions of
mRNA. The functions of mRNA to be interfered with include
10 all vital functions such as, for example, translocation of
the RNA to the site of protein translation, translation of
protein from the RNA, splicing of the RNA to yield one or
more mRNA species, and catalytic activity which may be
engaged in by the RNA. Binding of specific protein(s) to
15 the RNA may also be interfered with by antisense
oligonucleotide hybridization to the RNA.

The overall effect of interference with mRNA function
is modulation of expression of FAK. In the context of this
invention "modulation" means either inhibition or
20 stimulation; i.e., either a decrease or increase in
expression. This modulation can be measured in ways which
are routine in the art, for example by Northern blot assay
of mRNA expression, or reverse transcriptase PCR, as taught
in the examples of the instant application or by Western
25 blot or ELISA assay of protein expression, or by an
immunoprecipitation assay of protein expression. Effects
on cell proliferation or tumor cell growth can also be
measured, as taught in the examples of the instant
application. Inhibition is presently preferred.

30   The oligonucleotides of this invention can be used in
diagnostics, therapeutics, prophylaxis, and as research
reagents and in kits. Since the oligonucleotides of this
invention hybridize to nucleic acids encoding FAK,
sandwich, colorimetric and other assays can easily be
35 constructed to exploit this fact. Provision of means for

detecting hybridization of oligonucleotide with the FAK
genes or mRNA can routinely be accomplished. Such
provision may include enzyme conjugation, radiolabelling or
any other suitable detection systems. Kits for detecting
5 the presence or absence of FAK may also be prepared.

The present invention is also suitable for diagnosing
abnormal inflammatory states or certain cancers in tissue
or other samples from patients suspected of having an
autoimmune or inflammatory disease such as hepatitis or
10 cancers such as those of the colon, liver or lung, and
lymphomas. A number of assays may be formulated employing
the present invention, which assays will commonly comprise
contacting a tissue sample with an oligonucleotide of the
invention under conditions selected to permit detection
15 and, usually, quantitation of such inhibition. In the
context of this invention, to "contact" tissues or cells
with an oligonucleotide or oligonucleotides means to add
the oligonucleotide(s), usually in a liquid carrier, to a
cell suspension or tissue sample, either *in vitro* or *ex*
20 *vivo*, or to administer the oligonucleotide(s) to cells or
tissues within an animal.

The oligonucleotides of this invention may also be
used for research purposes. Thus, the specific
hybridization exhibited by the oligonucleotides may be used
25 for assays, purifications, cellular product preparations
and in other methodologies which may be appreciated by
persons of ordinary skill in the art.

In the context of this invention, the term
"oligonucleotide" refers to an oligomer or polymer of
30 ribonucleic acid or deoxyribonucleic acid. This term
includes oligonucleotides composed of naturally-occurring
nucleobases, sugars and covalent intersugar (backbone)
linkages as well as oligonucleotides having non-naturally-
occurring portions which function similarly. Such modified
35 or substituted oligonucleotides are often preferred over

native forms because of desirable properties such as, for
example, enhanced cellular uptake, enhanced binding to
target and increased stability in the presence of
nucleases.

5   The antisense compounds in accordance with this
invention preferably comprise from about 5 to about 50
nucleobases. Particularly preferred are antisense
oligonucleotides comprising from about 8 to about 30
nucleobases (i.e. from about 8 to about 30 linked

10 nucleosides). As is known in the art, a nucleoside is a
base-sugar combination. The base portion of the nucleoside
is normally a heterocyclic base. The two most common
classes of such heterocyclic bases are the purines and the
pyrimidines. Nucleotides are nucleosides that further

15 include a phosphate group covalently linked to the sugar
portion of the nucleoside. For those nucleosides that
include a pentofuranosyl sugar, the phosphate group can be
linked to either the 2=, 3= or 5= hydroxyl moiety of the
sugar. In forming oligonucleotides, the phosphate groups

20 covalently link adjacent nucleosides to one another to form
a linear polymeric compound. In turn the respective ends
of this linear polymeric structure can be further joined to
form a circular structure, however, open linear structures
are generally preferred. Within the oligonucleotide

25 structure, the phosphate groups are commonly referred to as
forming the internucleoside backbone of the
oligonucleotide. The normal linkage or backbone of RNA and
DNA is a 3= to 5= phosphodiester linkage.

Specific examples of preferred antisense compounds

30 useful in this invention include oligonucleotides
containing modified backbones or non-natural
internucleoside linkages. As defined in this
specification, oligonucleotides having modified backbones
include those that retain a phosphorus atom in the backbone

35 and those that do not have a phosphorus atom in the

backbone. For the purposes of this specification, and as
sometimes referenced in the art, modified oligonucleotides
that do not have a phosphorus atom in their internucleoside
backbone can also be considered to be oligonucleosides.

5   Preferred modified oligonucleotide backbones include,
for example, phosphorothioates, chiral phosphorothioates,
phosphorodithioates, phosphotriesters,
aminoalkylphosphotriesters, methyl and other alkyl
phosphonates including 3=-alkylene phosphonates and chiral
10   phosphonates, phosphinates, phosphoramidates including 3=-
amino phosphoramidate and aminoalkylphosphoramidates,
thionophosphoramidates, thionoalkylphosphonates,
thionoalkylphosphotriesters, and boranophosphates having
normal 3=-5= linkages, 2=-5= linked analogs of these, and
15   those having inverted polarity wherein the adjacent pairs
of nucleoside units are linked 3=-5= to 5=-3= or 2=-5= to
5=-2=. Various salts, mixed salts and free acid forms are
also included.

            Representative United States patents that teach the
20   preparation of the above phosphorus-containing linkages
include, but are not limited to, U.S. Patents 3,687,808;
4,469,863; 4,476,301; 5,023,243; 5,177,196; 5,188,897;
5,264,423; 5,276,019; 5,278,302; 5,286,717; 5,321,131;
5,399,676; 5,405,939; 5,453,496; 5,455,233; 5,466,677;
25   5,476,925; 5,519,126; 5,536,821; 5,541,306; 5,550,111;
5,563,253; 5,571,799; 5,587,361; and 5,625,050.

            Preferred modified oligonucleotide backbones that do
not include a phosphorus atom therein have backbones that
are formed by short chain alkyl or cycloalkyl
30   internucleoside linkages, mixed heteroatom and alkyl or
cycloalkyl internucleoside linkages, or one or more short
chain heteroatomic or heterocyclic internucleoside
linkages. These include those having morpholino linkages
(formed in part from the sugar portion of a nucleoside);
35   siloxane backbones; sulfide, sulfoxide and sulfone

backbones; formacetyl and thioformacetyl backbones; methylene formacetyl and thioformacetyl backbones; alkene containing backbones; sulfamate backbones; methyleneimino and methylenehydrazino backbones; sulfonate and sulfonamide

5 backbones; amide backbones; and others having mixed N, O, S and CH$_2$ component parts.

Representative United States patents that teach the preparation of the above oligonucleosides include, but are not limited to, U.S. Patents 5,034,506; 5,166,315;

10 5,185,444; 5,214,134; 5,216,141; 5,235,033; 5,264,562; 5,264,564; 5,405,938; 5,434,257; 5,466,677; 5,470,967; 5,489,677; 5,541,307; 5,561,225; 5,596,086; 5,602,240; 5,610,289; 5,602,240; 5,608,046; 5,610,289; 5,618,704; 5,623,070; 5,663,312; 5,633,360; 5,677,437; and 5,677,439.

15   In other preferred oligonucleotide mimetics, both the sugar and the internucleoside linkage, i.e., the backbone, of the nucleotide units are replaced with novel groups. The base units are maintained for hybridization with an appropriate nucleic acid target compound. One such

20 oligomeric compound, an oligonucleotide mimetic that has been shown to have excellent hybridization properties, is referred to as a peptide nucleic acid (PNA). In PNA compounds, the sugar-backbone of an oligonucleotide is replaced with an amide containing backbone, in particular

25 an aminoethylglycine backbone. The nucleobases are retained and are bound directly or indirectly to aza nitrogen atoms of the amide portion of the backbone. Representative United States patents that teach the preparation of PNA compounds include, but are not limited

30 to, U.S. Patents 5,539,082; 5,714,331; and 5,719,262. Further teaching of PNA compounds can be found in Nielsen *et al.* (*Science*, **1991**, *254*, 1497-1500).

Most preferred embodiments of the invention are oligonucleotides with phosphorothioate backbones and

35 oligonucleosides with heteroatom backbones, and in

particular $-CH_2-NH-O-CH_2-$, $-CH_2-N(CH_3)-O-CH_2-$ [known as a
methylene (methylimino) or MMI backbone], $-CH_2-O-N(CH_3)$
$-CH_2-$, $-CH_2-N(CH_3)-N(CH_3)-CH_2-$ and $-O-N(CH_3)-CH_2-CH_2-$ [wherein
the native phosphodiester backbone is represented as $-O-P-$
5   $O-CH_2-$] of the above referenced U.S. patent 5,489,677, and
the amide backbones of the above referenced U.S. patent
5,602,240. Also preferred are oligonucleotides having
morpholino backbone structures of the above-referenced U.S.
patent 5,034,506.

10   Modified oligonucleotides may also contain one or
more substituted sugar moieties. Preferred
oligonucleotides comprise one of the following at the 2'
position: OH; F; O-, S-, or N-alkyl, O-alkyl-O-alkyl, O-,
S-, or N-alkenyl, or O-, S- or N-alkynyl, wherein the
15   alkyl, alkenyl and alkynyl may be substituted or
unsubstituted C_1 to C_{10} alkyl or C_2 to C_{10} alkenyl and
alkynyl. Particularly preferred are $O[(CH_2)_nO]_mCH_3$,
$O(CH_2)_nOCH_3$, $O(CH_2)_2ON(CH_3)_2$, $O(CH_2)_nNH_2$, $O(CH_2)_nCH_3$, $O(CH_2)_nONH_2$,
and $O(CH_2)_nON[(CH_2)_nCH_3)]_2$, where n and m are from 1 to about
20   10. Other preferred oligonucleotides comprise one of the
following at the 2= position: C_1 to C_{10} lower alkyl,
substituted lower alkyl, alkaryl, aralkyl, O-alkaryl or O-
aralkyl, SH, SCH_3, OCN, Cl, Br, CN, CF_3, OCF_3, $SOCH_3$, SO_2CH_3,
ONO_2, NO_2, N_3, NH_2, heterocycloalkyl, heterocycloalkaryl,
25   aminoalkylamino, polyalkylamino, substituted silyl, an RNA
cleaving group, a reporter group, an intercalator, a group
for improving the pharmacokinetic properties of an
oligonucleotide, or a group for improving the
pharmacodynamic properties of an oligonucleotide, and other
30   substituents having similar properties. A preferred
modification includes 2'-methoxyethoxy ($2'-O-CH_2CH_2OCH_3$, also
known as 2'-O-(2-methoxyethyl) or 2'-MOE) (Martin *et al.*,
Helv. Chim. Acta **1995,** *78*, 486-504) i.e., an alkoxyalkoxy
group. A further preferred modification includes 2'-
35   dimethylaminooxyethoxy, i.e., a $O(CH_2)_2ON(CH_3)_2$ group, also

known as 2'-DMAOE, and 2'-dimethylamino-ethoxyethoxy (2'-DMAEOE), i.e., 2'-O-CH_2-O-CH_2-N$(CH_2)_2$.

Other preferred modifications include 2'-methoxy (2'-O-CH_3), 2'-aminopropoxy (2'-O$CH_2CH_2CH_2NH_2$) and 2'-fluoro (2'-
5 F). Similar modifications may also be made at other positions on the oligonucleotide, particularly the 3' position of the sugar on the 3' terminal nucleotide or in 2=-5= linked oligonucleotides and the 5' position of 5' terminal nucleotide. Oligonucleotides may also have sugar
10 mimetics such as cyclobutyl moieties in place of the pentofuranosyl sugar. Representative U.S. patents that teach the preparation of such modified sugars structures include, but are not limited to, U.S. patents 4,981,957; 5,118,800; 5,319,080; 5,359,044; 5,393,878; 5,446,137;
15 5,466,786; 5,514,785; 5,519,134; 5,567,811; 5,576,427; 5,591,722; 5,597,909; 5,610,300; 5,627,0531 5,639,873; 5,646,265; 5,658,873; 5,670,633; and 5,700,920.

Oligonucleotides may also include nucleobase (often referred to in the art simply as "base") modifications or
20 substitutions. As used herein, "unmodified" or "natural" nucleobases include the purine bases adenine (A) and guanine (G), and the pyrimidine bases thymine (T), cytosine (C) and uracil (U). Modified nucleobases include other synthetic and natural nucleobases such as 5-methylcytosine
25 (5-me-C or m5c), 5-hydroxymethyl cytosine, xanthine, hypoxanthine, 2-aminoadenine, 6-methyl and other alkyl derivatives of adenine and guanine, 2-propyl and other alkyl derivatives of adenine and guanine, 2-thiouracil, 2-thiothymine and 2-thiocytosine, 5-halouracil and cytosine,
30 5-propynyl uracil and cytosine, 6-azo uracil, cytosine and thymine, 5-uracil (pseudouracil), 4-thiouracil, 8-halo, 8-amino, 8-thiol, 8-thioalkyl, 8-hydroxyl and other 8-substituted adenines and guanines, 5-halo particularly 5-bromo, 5-trifluoromethyl and other 5-substituted uracils
35 and cytosines, 7-methylguanine and 7-methyladenine, 8-

azaguanine and 8-azaadenine, 7-deazaguanine and 7-
deazaadenine and 3-deazaguanine and 3-deazaadenine.
Further nucleobases include those disclosed in U.S. patent
3,687,808, those disclosed in the *Concise Encyclopedia Of*
5   *Polymer Science And Engineering* **1990**, pages 858-859,
Kroschwitz, J.I., ed. John Wiley & Sons, those disclosed by
Englisch *et al.* (*Angewandte Chemie, International Edition*
1991, *30*, 613-722), and those disclosed by Sanghvi, Y.S.,
Chapter 15, *Antisense Research and Applications* **1993**, pages
10 289-302, Crooke, S.T. and Lebleu, B., ed., CRC Press.
Certain of these nucleobases are particularly useful for
increasing the binding affinity of the oligomeric compounds
of the invention. These include 5-substituted pyrimidines,
6-azapyrimidines and N-2, N-6 and O-6 substituted purines,
15 including 2-aminopropyladenine, 5-propynyluracil and 5-
propynylcytosine. 5-methylcytosine substitutions have been
shown to increase nucleic acid duplex stability by 0.6-1.2°C
(Sanghvi, Y.S., Crooke, S.T. and Lebleu, B., eds.,
Antisense Research and Applications **1993**, CRC Press, Boca
20 Raton, pages 276-278) and are presently preferred base
substitutions, even more particularly when combined with
2'-O-methoxyethyl sugar modifications.
      Representative U.S. patents that teach the
preparation of certain of the above noted modified
25 nucleobases as well as other modified nucleobases include,
but are not limited to, the above noted U.S. patent
3,687,808, as well as U.S. patents 4,845,205; 5,130,302;
5,134,066; 5,175,273; 5,367,066; 5,432,272; 5,457,187;
5,459,255; 5,484,908; 5,502,177; 5,525,711; 5,552,540;
30 5,587,469; 5,594,121, 5,596,091; 5,614,617; and 5,681,941.
      Another modification of the oligonucleotides of the
invention involves chemically linking to the
oligonucleotide one or more moieties or conjugates which
enhance the activity, cellular distribution or cellular

uptake of the oligonucleotide. Such moieties include but are not limited to lipid moieties such as a cholesterol moiety (Letsinger *et al., Proc. Natl. Acad. Sci. USA* **1989**, *86*, 6553-6556), cholic acid (Manoharan *et al., Bioorg. Med.*

5 *Chem. Lett.* **1994**, *4*, 1053-1059), a thioether, e.g., hexyl-S-tritylthiol (Manoharan *et al., Ann. N.Y. Acad. Sci.* **1992**, *660*, 306-309; Manoharan *et al., Bioorg. Med. Chem. Let.* **1993**, *3*, 2765-2770), a thiocholesterol (Oberhauser *et al., Nucl. Acids Res.* **1992**, *20*, 533-538), an aliphatic chain,

10 e.g., dodecandiol or undecyl residues (Saison-Behmoaras *et al., EMBO J.* **1991**, *10*, 1111-1118; Kabanov *et al., FEBS Lett.* **1990**, *259*, 327-330; Svinarchuk *et al., Biochimie* **1993**, *75*, 49-54), a phospholipid, e.g., di-hexadecyl-*rac*-glycerol or triethylammonium 1,2-di-O-hexadecyl-*rac*-

15 glycero-3-H-phosphonate (Manoharan *et al., Tetrahedron Lett.* **1995**, *36*, 3651-3654; Shea *et al., Nucl. Acids Res.* **1990**, *18,* 3777-3783), a polyamine or a polyethylene glycol chain (Manoharan *et al., Nucleosides & Nucleotides* **1995**, *14*, 969-973), or adamantane acetic acid (Manoharan *et al.,*

20 *Tetrahedron Lett.* **1995**, *36*, 3651-3654), a palmityl moiety (Mishra *et al., Biochim. Biophys. Acta* **1995**, *1264*, 229-237), or an octadecylamine or hexylamino-carbonyl-oxycholesterol moiety (Crooke *et al., J. Pharmacol. Exp. Ther.* **1996**, *277*, 923-937).

25   Representative U.S. patents that teach the preparation of such oligonucleotide conjugates include, but are not limited to, U.S. patents 4,828,979; 4,948,882; 5,218,105; 5,525,465; 5,541,313; 5,545,730; 5,552,538; 5,578,717; 5,580,731; 5,580,731; 5,591,584; 5,109,124;

30 5,118,802; 5,138,045; 5,414,077; 5,486,603; 5,512,439; 5,578,718; 5,608,046; 4,587,044; 4,605,735; 4,667,025; 4,762,779; 4,789,737; 4,824,941; 4,835,263; 4,876,335; 4,904,582; 4,958,013; 5,082,830; 5,112,963; 5,214,136; 5,082,830; 5,112,963; 5,214,136; 5,245,022; 5,254,469;

5,258,506; 5,262,536; 5,272,250; 5,292,873; 5,317,098;

5,371,241; 5,391,723; 5,416,203; 5,451,463; 5,510,475;

5,512,667; 5,514,785; 5,565,552; 5,567,810; 5,574,142;

5,585,481; 5,587,371; 5,595,726; 5,597,696; 5,599,923;

5 5,599,928

and 5,688,941.

    The present invention also includes oligonucleotides
which are chimeric oligonucleotides. "Chimeric"
oligonucleotides or "chimeras," in the context of this
10 invention, are oligonucleotides which contain two or more
chemically distinct regions, each made up of at least one
nucleotide. These oligonucleotides typically contain at
least one region wherein the oligonucleotide is modified so
as to confer upon the oligonucleotide increased resistance
15 to nuclease degradation, increased cellular uptake, and/or
increased binding affinity for the target nucleic acid. An
additional region of the oligonucleotide may serve as a
substrate for enzymes capable of cleaving RNA:DNA or
RNA:RNA hybrids. By way of example, RNase H is a cellular
20 endonuclease which cleaves the RNA strand of an RNA:DNA
duplex. Activation of RNase H, therefore, results in
cleavage of the RNA target, thereby greatly enhancing the
efficiency of antisense inhibition of gene expression.
Cleavage of the RNA target can be routinely detected by gel
25 electrophoresis and, if necessary, associated nucleic acid
hybridization techniques known in the art. This RNAse H-
mediated cleavage of the RNA target is distinct from the
use of ribozymes to cleave nucleic acids. Ribozymes are not
comprehended by the present invention.

30   Examples of chimeric oligonucleotides include but are
not limited to "gapmers," in which three distinct regions
are present, normally with a central region flanked by two
regions which are chemically equivalent to each other but
distinct from the gap. A preferred example of a gapmer is
35 an oligonucleotide in which a central portion (the "gap")

of the oligonucleotide serves as a substrate for RNase H
and is preferably composed of 2'-deoxynucleotides, while
the flanking portions (the 5' and 3' "wings") are modified
to have greater affinity for the target RNA molecule but

5 are unable to support nuclease activity (e.g., fluoro- or
2'-O-methoxyethyl- substituted). Chimeric oligonucleotides
are not limited to those with modifications on the sugar,
but may also include oligonucleosides or oligonucleotides
with modified backbones, e.g., with regions of

10 phosphorothioate (P=S) and phosphodiester (P=O) backbone
linkages or with regions of MMI and P=S backbone linkages.
Other chimeras include "wingmers," also known in the art as
"hemimers," that is, oligonucleotides with two distinct
regions. In a preferred example of a wingmer, the 5'

15 portion of the oligonucleotide serves as a substrate for
RNase H and is preferably composed of 2'-deoxynucleotides,
whereas the 3' portion is modified in such a fashion so as
to have greater affinity for the target RNA molecule but is
unable to support nuclease activity (e.g., 2'-fluoro- or

20 2'-O-methoxyethyl- substituted), or vice-versa. In one
embodiment, the oligonucleotides of the present invention
contain a 2'-O-methoxyethyl (2'-O-$CH_2CH_2OCH_3$) modification on
the sugar moiety of at least one nucleotide. This
modification has been shown to increase both affinity of

25 the oligonucleotide for its target and nuclease resistance
of the oligonucleotide. According to the invention, one, a
plurality, or all of the nucleotide subunits of the
oligonucleotides of the invention may bear a 2'-O-
methoxyethyl (-O-$CH_2CH_2OCH_3$) modification. Oligonucleotides

30 comprising a plurality of nucleotide subunits having a 2'-
O-methoxyethyl modification can have such a modification on
any of the nucleotide subunits within the oligonucleotide,
and may be chimeric oligonucleotides. Aside from or in
addition to 2'-O-methoxyethyl modifications,

35 oligonucleotides containing other modifications which

enhance antisense efficacy, potency or target affinity are
also preferred. Chimeric oligonucleotides comprising one
or more such modifications are presently preferred.

5   The oligonucleotides used in accordance with this
invention may be conveniently and routinely made through
the well-known technique of solid phase synthesis.
Equipment for such synthesis is sold by several vendors
including Applied Biosystems. Any other means for such
synthesis may also be employed; the actual synthesis of the
10   oligonucleotides is well within the talents of the
routineer. It is well known to use similar techniques to
prepare oligonucleotides such as the phosphorothioates and
2'-alkoxy or 2'-alkoxyalkoxy derivatives, including 2'-O-
methoxyethyl oligonucleotides (Martin, P., *Helv. Chim. Acta*
15   **1995,** *78*, 486-504). It is also well known to use similar
techniques and commercially available modified amidites and
controlled-pore glass (CPG) products such as biotin,
fluorescein, acridine or psoralen-modified amidites and/or
CPG (available from Glen Research, Sterling, VA) to
20   synthesize fluorescently labeled, biotinylated or other
conjugated oligonucleotides.

The antisense compounds of the present invention
include bioequivalent compounds, including pharmaceutically
acceptable salts and prodrugs. This is intended to
25   encompass any pharmaceutically acceptable salts, esters, or
salts of such esters, or any other compound which, upon
administration to an animal including a human, is capable
of providing (directly or indirectly) the biologically
active metabolite or residue thereof. Accordingly, for
30   example, the disclosure is also drawn to pharmaceutically
acceptable salts of the nucleic acids of the invention and
prodrugs of such nucleic acids. Pharmaceutically
acceptable salts are physiologically and pharmaceutically
acceptable salts of the nucleic acids of the invention:
35   *i.e.,* salts that retain the desired biological activity of

the parent compound and do not impart undesired toxicological effects thereto (see, for example, Berge *et al.*, "Pharmaceutical Salts," *J. of Pharma Sci.* **1977**, *66,* 1-19).

5   For oligonucleotides, examples of pharmaceutically acceptable salts include but are not limited to (a) salts formed with cations such as sodium, potassium, ammonium, magnesium, calcium, polyamines such as spermine and spermidine, *etc.;* (b) acid addition salts formed with

10 inorganic acids, for example hydrochloric acid, hydrobromic acid, sulfuric acid, phosphoric acid, nitric acid and the like; (c) salts formed with organic acids such as, for example, acetic acid, oxalic acid, tartaric acid, succinic acid, maleic acid, fumaric acid, gluconic acid, citric

15 acid, malic acid, ascorbic acid, benzoic acid, tannic acid, palmitic acid, alginic acid, polyglutamic acid, naphthalenesulfonic acid, methanesulfonic acid, p-toluenesulfonic acid, naphthalenedisulfonic acid, polygalacturonic acid, and the like; and (d) salts formed

20 from elemental anions such as chlorine, bromine, and iodine.

The oligonucleotides of the invention may additionally or alternatively be prepared to be delivered in a Aprodrug form. The term Aprodrug indicates a

25 therapeutic agent that is prepared in an inactive form that is converted to an active form (i.e., drug) within the body or cells thereof by the action of endogenous enzymes or other chemicals and/or conditions. In particular, prodrug versions of the oligonucleotides of the invention are

30 prepared as SATE [(S-acetyl-2-thioethyl) phosphate] derivatives according to the methods disclosed in WO 93/24510 to Gosselin *et al.*, published December 9, 1993.

For therapeutic or prophylactic treatment, oligonucleotides are administered in accordance with this

35 invention. Oligonucleotide compounds of the invention may

be formulated in a pharmaceutical composition, which may include pharmaceutically acceptable carriers, thickeners, diluents, buffers, preservatives, surface active agents, neutral or cationic lipids, lipid complexes, liposomes,

5   penetration enhancers, carrier compounds and other pharmaceutically acceptable carriers or excipients and the like in addition to the oligonucleotide. Such compositions and formulations are comprehended by the present invention.

Pharmaceutical compositions comprising the

10 oligonucleotides of the present invention may include penetration enhancers in order to enhance the alimentary delivery of the oligonucleotides. Penetration enhancers may be classified as belonging to one of five broad categories, *i.e.*, fatty acids, bile salts, chelating agents,

15 surfactants and non-surfactants (Lee *et al.*, *Critical Reviews in Therapeutic Drug Carrier Systems* **1991**, *8,* 91-192; Muranishi, *Critical Reviews in Therapeutic Drug Carrier Systems* **1990**, *7,* 1-33). One or more penetration enhancers from one or more of these broad categories may be

20 included.

Various fatty acids and their derivatives which act as penetration enhancers include, for example, oleic acid, lauric acid, capric acid, myristic acid, palmitic acid, stearic acid, linoleic acid, linolenic acid, dicaprate,

25 tricaprate, recinleate, monoolein (a.k.a. 1-monooleoyl-*rac*-glycerol), dilaurin, caprylic acid, arachidonic acid, glyceryl 1-monocaprate, 1-dodecylazacycloheptan-2-one, acylcarnitines, acylcholines, mono- and di-glycerides and physiologically acceptable salts thereof (*i.e.*, oleate,

30 laurate, caprate, myristate, palmitate, stearate, linoleate, *etc.*) (Lee *et al.*, *Critical Reviews in Therapeutic Drug Carrier Systems* **1991**, page 92; Muranishi, *Critical Reviews in Therapeutic Drug Carrier Systems* **1990**,

7, 1; El-Hariri *et al.*, *J. Pharm. Pharmacol.* **1992** *44,* 651-
654).

The physiological roles of bile include the
facilitation of dispersion and absorption of lipids and
5 fat-soluble vitamins (Brunton, Chapter 38 *In: Goodman &
Gilman's The Pharmacological Basis of Therapeutics*, 9th
Ed., Hardman *et al.*, eds., McGraw-Hill, New York, NY, **1996,**
pages 934-935). Various natural bile salts, and their
synthetic derivatives, act as penetration enhancers. Thus,
10 the term "bile salt" includes any of the naturally
occurring components of bile as well as any of their
synthetic derivatives.

Complex formulations comprising one or more
penetration enhancers may be used. For example, bile salts
15 may be used in combination with fatty acids to make complex
formulations.

Chelating agents include, but are not limited to,
disodium ethylenediaminetetraacetate (EDTA), citric acid,
salicylates (*e.g.*, sodium salicylate, 5-methoxysalicylate
20 and homovanilate), *N*-acyl derivatives of collagen,
laureth-9 and *N*-amino acyl derivatives of beta-diketones
(enamines)[Lee *et al.*, *Critical Reviews in Therapeutic Drug
Carrier Systems* **1991**, page 92; Muranishi, *Critical Reviews
in Therapeutic Drug Carrier Systems* **1990**, 7, 1-33; Buur et
25 *al.*, *J. Control Rel.* **1990**, *14,* 43-51). Chelating agents
have the added advantage of also serving as DNase
inhibitors.

Surfactants include, for example, sodium lauryl
sulfate, polyoxyethylene-9-lauryl ether and
30 polyoxyethylene-20-cetyl ether (Lee *et al.*, *Critical
Reviews in Therapeutic Drug Carrier Systems* **1991**, page 92);
and perfluorochemical emulsions, such as FC-43 (Takahashi
et al., *J. Pharm. Phamacol.* **1988**, *40,* 252-257).

Non-surfactants include, for example, unsaturated cyclic ureas, 1-alkyl- and 1-alkenylazacyclo-alkanone derivatives (Lee *et al.*, *Critical Reviews in Therapeutic Drug Carrier Systems* **1991**, page 92); and non-steroidal anti-inflammatory agents such as diclofenac sodium, indomethacin and phenylbutazone (Yamashita *et al.*, *J. Pharm. Pharmacol.* **1987**, *39,* 621-626).

As used herein, "carrier compound" refers to a nucleic acid, or analog thereof, which is inert (*i.e.*, does not possess biological activity *per se*) but is recognized as a nucleic acid by *in vivo* processes that reduce the bioavailability of a nucleic acid having biological activity by, for example, degrading the biologically active nucleic acid or promoting its removal from circulation. The coadministration of a nucleic acid and a carrier compound, typically with an excess of the latter substance, can result in a substantial reduction of the amount of nucleic acid recovered in the liver, kidney or other extracirculatory reservoirs, presumably due to competition between the carrier compound and the nucleic acid for a common receptor.

In contrast to a carrier compound, a "pharmaceutically acceptable carrier" (excipient) is a pharmaceutically acceptable solvent, suspending agent or any other pharmacologically inert vehicle for delivering one or more nucleic acids to an animal. The pharmaceutically acceptable carrier may be liquid or solid and is selected with the planned manner of administration in mind so as to provide for the desired bulk, consistency, *etc.*, when combined with a nucleic acid and the other components of a given pharmaceutical composition. Typical pharmaceutically acceptable carriers include, but are not limited to, binding agents (*e.g.*, pregelatinized maize starch, polyvinylpyrrolidone or hydroxypropyl

methylcellulose, *etc.*); fillers (*e.g.*, lactose and other sugars, microcrystalline cellulose, pectin, gelatin, calcium sulfate, ethyl cellulose, polyacrylates or calcium hydrogen phosphate, *etc.*); lubricants (*e.g.*, magnesium

5 stearate, talc, silica, colloidal silicon dioxide, stearic acid, metallic stearates, hydrogenated vegetable oils, corn starch, polyethylene glycols, sodium benzoate, sodium acetate, *etc.*); disintegrates (*e.g.*, starch, sodium starch glycolate, *etc.*); or wetting agents (*e.g.*, sodium lauryl

10 sulphate, *etc.*). Sustained release oral delivery systems and/or enteric coatings for orally administered dosage forms are described in U.S. patents 4,704,295; 4,556,552; 4,309,406; and 4,309,404.

The compositions of the present invention may

15 additionally contain other adjunct components conventionally found in pharmaceutical compositions, at their art-established usage levels. Thus, for example, the compositions may contain additional compatible pharmaceutically-active materials such as, *e.g.*,

20 antipruritics, astringents, local anesthetics or anti-inflammatory agents, or may contain additional materials useful in physically formulating various dosage forms of the composition of present invention, such as dyes, flavoring agents, preservatives, antioxidants,

25 opacifiers, thickening agents and stabilizers. However, such materials, when added, should not unduly interfere with the biological activities of the components of the compositions of the invention.

Regardless of the method by which the

30 oligonucleotides of the invention are introduced into a patient, colloidal dispersion systems may be used as delivery vehicles to enhance the *in vivo* stability of the oligonucleotides and/or to target the oligonucleotides to a particular organ, tissue or cell type. Colloidal

35 dispersion systems include, but are not limited to,

macromolecule complexes, nanocapsules, microspheres, beads
and lipid-based systems including oil-in-water emulsions,
micelles, mixed micelles, liposomes and
lipid:oligonucleotide complexes of uncharacterized

5 structure. A preferred colloidal dispersion system is a
plurality of liposomes. Liposomes are microscopic spheres
having an aqueous core surrounded by one or more outer
layers made up of lipids arranged in a bilayer
configuration (see, generally, Chonn *et al.*, *Current Op.*

10 *Biotech.* **1995**, *6,* 698-708).

The pharmaceutical compositions of the present
invention may be administered in a number of ways depending
upon whether local or systemic treatment is desired and
upon the area to be treated. Administration may be topical

15 (including ophthalmic, vaginal, rectal, intranasal,
epidermal, and transdermal), oral or parenteral.
Parenteral administration includes intravenous drip,
subcutaneous, intraperitoneal or intramuscular injection,
pulmonary administration, e.g., by inhalation or

20 insufflation, or intracranial, e.g., intrathecal or
intraventricular, administration. Oligonucleotides with at
least one 2'-O-methoxyethyl modification are believed to be
particularly useful for oral administration.

Formulations for topical administration may include

25 transdermal patches, ointments, lotions, creams, gels,
drops, suppositories, sprays, liquids and powders.
Conventional pharmaceutical carriers, aqueous, powder or
oily bases, thickeners and the like may be necessary or
desirable. Coated condoms, gloves and the like may also be

30 useful.

Compositions for oral administration include powders
or granules, suspensions or solutions in water or non-
aqueous media, capsules, sachets or tablets. Thickeners,
flavoring agents, diluents, emulsifiers, dispersing aids or

35 binders may be desirable.

Compositions for parenteral administration may include sterile aqueous solutions which may also contain buffers, diluents and other suitable additives. In some cases it may be more effective to treat a patient with an

5 oligonucleotide of the invention in conjunction with other traditional therapeutic modalities in order to increase the efficacy of a treatment regimen. In the context of the invention, the term "treatment regimen" is meant to encompass therapeutic, palliative and prophylactic

10 modalities. For example, a patient may be treated with conventional chemotherapeutic agents, particularly those used for tumor and cancer treatment. Examples of such chemotherapeutic agents include but are not limited to daunorubicin, daunomycin, dactinomycin, doxorubicin,

15 epirubicin, idarubicin, esorubicin, bleomycin, mafosfamide, ifosfamide, cytosine arabinoside, bis-chloroethylnitrosurea, busulfan, mitomycin C, actinomycin D, mithramycin, prednisone, hydroxyprogesterone, testosterone, tamoxifen, dacarbazine, procarbazine,

20 hexamethylmelamine, pentamethylmelamine, mitoxantrone, amsacrine, chlorambucil, methylcyclohexylnitrosurea, nitrogen mustards, melphalan, cyclophosphamide, 6-mercaptopurine, 6-thioguanine, cytarabine (CA), 5-azacytidine, hydroxyurea, deoxycoformycin, 4-

25 hydroxyperoxycyclophosphoramide, 5-fluorouracil (5-FU), 5-fluorodeoxyuridine (5-FUdR), methotrexate (MTX), colchicine, taxol, vincristine, vinblastine, etoposide, trimetrexate, teniposide, cisplatin and diethylstilbestrol (DES). See, generally, *The Merck Manual of Diagnosis and*

30 *Therapy*, 15th Ed. **1987**, pp. 1206-1228; Berkow *et al.*, eds., Rahway, N.J. When used with the compounds of the invention, such chemotherapeutic agents may be used individually (*e.g.*, 5-FU and oligonucleotide), sequentially (*e.g.*, 5-FU and oligonucleotide for a period of time

35 followed by MTX and oligonucleotide), or in combination

with one or more other such chemotherapeutic agents (*e.g.*, 5-FU, MTX and oligonucleotide, or 5-FU, radiotherapy and oligonucleotide).

5   The formulation of therapeutic compositions and their subsequent administration is believed to be within the skill of those in the art. Dosing is dependent on severity and responsiveness of the disease state to be treated, with the course of treatment lasting from several days to several months, or until a cure is effected or a diminution
10   of the disease state is achieved. Optimal dosing schedules can be calculated from measurements of drug accumulation in the body of the patient. Persons of ordinary skill can easily determine optimum dosages, dosing methodologies and repetition rates. Optimum dosages may vary depending on
15   the relative potency of individual oligonucleotides, and can generally be estimated based on EC_{50}s found to be effective *in vitro* and in *in vivo* animal models. In general, dosage is from 0.01 μg to 100 g per kg of body weight, and may be given once or more daily, weekly,
20   monthly or yearly, or even once every 2 to 20 years. Persons of ordinary skill in the art can easily estimate repetition rates for dosing based on measured residence times and concentrations of the drug in bodily fluids or tissues. Following successful treatment, it may be
25   desirable to have the patient undergo maintenance therapy to prevent the recurrence of the disease state, wherein the oligonucleotide is administered in maintenance doses; ranging from 0.01 μg to 100 g per kg of body weight, once or more daily, to once every 20 years.
30   The following examples illustrate the present invention and are not intended to limit the same.

EXAMPLES

EXAMPLE 1: Synthesis of Oligonucleotides

Unmodified oligodeoxynucleotides are synthesized on
an automated DNA synthesizer (Applied Biosystems model
380B) using standard phosphoramidite chemistry with
oxidation by iodine. ß-cyanoethyldiisopropyl-
phosphoramidites are purchased from Applied Biosystems
(Foster City, CA). For phosphorothioate oligonucleotides,
the standard oxidation bottle was replaced by a 0.2 M
solution of ^{3}H-1,2-benzodithiole-3-one 1,1-dioxide in
acetonitrile for the stepwise thiation of the phosphite
linkages. The thiation cycle wait step was increased to 68
seconds and was followed by the capping step. Cytosines
may be 5-methyl cytosines. (5-methyl deoxycytidine
phosphoramidites available from Glen Research, Sterling, VA
or Amersham Pharmacia Biotech, Piscataway, NJ)

2'-methoxy oligonucleotides are synthesized using 2'-
methoxy ß-cyanoethyldiisopropyl-phosphoramidites
(Chemgenes, Needham, MA) and the standard cycle for
unmodified oligonucleotides, except the wait step after
pulse delivery of tetrazole and base is increased to 360
seconds. Other 2'-alkoxy oligonucleotides are synthesized
by a modification of this method, using appropriate 2'-
modified amidites such as those available from Glen
Research, Inc., Sterling, VA.

2'-fluoro oligonucleotides are synthesized as
described in Kawasaki et al. (J. Med. Chem. **1993**, *36*, 831-
841). Briefly, the protected nucleoside N^6-benzoyl-2'-
deoxy-2'-fluoroadenosine is synthesized utilizing
commercially available 9-ß-D-arabinofuranosyladenine as
starting material and by modifying literature procedures
whereby the 2'-a-fluoro atom is introduced by a S$_N$2-
displacement of a 2'-ß-O-trifyl group. Thus N^6-benzoyl-9-ß-
D-arabinofuranosyladenine is selectively protected in
moderate yield as the 3',5'-ditetrahydropyranyl (THP)

intermediate. Deprotection of the THP and N^6-benzoyl groups
is accomplished using standard methodologies and standard
methods are used to obtain the 5'-dimethoxytrityl- (DMT)
and 5'-DMT-3'-phosphoramidite intermediates.

5   The synthesis of 2'-deoxy-2'-fluoroguanosine is
accomplished using tetraisopropyldisiloxanyl (TPDS)
protected 9-ß-D-arabinofuranosylguanine as starting
material, and conversion to the intermediate diisobutyryl-
arabinofuranosylguanosine. Deprotection of the TPDS group

10 is followed by protection of the hydroxyl group with THP to
give diisobutyryl di-THP protected arabinofuranosylguanine.
Selective O-deacylation and triflation is followed by
treatment of the crude product with fluoride, then
deprotection of the THP groups. Standard methodologies are

15 used to obtain the 5'-DMT- and 5'-DMT-3'-phosphoramidites.
          Synthesis of 2'-deoxy-2'-fluorouridine is
accomplished by the modification of a known procedure in
which 2, 2'-anhydro-1-ß-D-arabinofuranosyluracil is treated
with 70% hydrogen fluoride-pyridine. Standard procedures

20 are used to obtain the 5'-DMT and 5'-DMT-
3'phosphoramidites.
          2'-deoxy-2'-fluorocytidine is synthesized via
amination of 2'-deoxy-2'-fluorouridine, followed by
selective protection to give N^4-benzoyl-2'-deoxy-2'-

25 fluorocytidine. Standard procedures are used to obtain the
5'-DMT and 5'-DMT-3'phosphoramidites.
          2'-(2-methoxyethyl)-modified amidites were
synthesized according to Martin, P. (*Helv. Chim. Acta* **1995**,
78, 486-506). For ease of synthesis, the last nucleotide

30 may be a deoxynucleotide. 2'-O-$CH_2CH_2OCH_3$-cytosines may be
5-methyl cytosines.

Synthesis of 5-Methyl cytosine monomers:

2,2'-Anhydro[1-(ß-D-arabinofuranosyl)-5-methyluridine]:

     5-Methyluridine (ribosylthymine, commercially available through Yamasa, Choshi, Japan) (72.0 g, 0.279 M),

5 diphenylcarbonate (90.0 g, 0.420 M) and sodium bicarbonate (2.0 g, 0.024 M) were added to DMF (300 mL). The mixture was heated to reflux, with stirring, allowing the evolved carbon dioxide gas to be released in a controlled manner. After 1 hour, the slightly darkened solution was

10 concentrated under reduced pressure. The resulting syrup was poured into diethylether (2.5 L), with stirring. The product formed a gum. The ether was decanted and the residue was dissolved in a minimum amount of methanol (ca. 400 mL). The solution was poured into fresh ether (2.5 L)

15 to yield a stiff gum. The ether was decanted and the gum was dried in a vacuum oven (60°C at 1 mm Hg for 24 h) to give a solid which was crushed to a light tan powder (57 g, 85% crude yield). The material was used as is for further reactions.

20 2'-O-Methoxyethyl-5-methyluridine:

     2,2'-Anhydro-5-methyluridine (195 g, 0.81 M), tris(2-methoxyethyl)borate (231 g, 0.98 M) and 2-methoxyethanol (1.2 L) were added to a 2 L stainless steel pressure vessel and placed in a pre-heated oil bath at 160°C. After heating

25 for 48 hours at 155-160°C, the vessel was opened and the solution evaporated to dryness and triturated with MeOH (200 mL). The residue was suspended in hot acetone (1 L). The insoluble salts were filtered, washed with acetone (150 mL) and the filtrate evaporated. The residue (280 g) was

30 dissolved in CH_3CN (600 mL) and evaporated. A silica gel column (3 kg) was packed in CH_2Cl_2/acetone/MeOH (20:5:3) containing 0.5% Et_3NH. The residue was dissolved in CH_2Cl_2 (250 mL) and adsorbed onto silica (150 g) prior to loading

onto the column. The product was eluted with the packing
solvent to give 160 g (63%) of product.

2'-O-Methoxyethyl-5'-O-dimethoxytrityl-5-methyluridine:

5   2'-O-Methoxyethyl-5-methyluridine (160 g, 0.506 M).
was co-evaporated with pyridine (250 mL) and the dried
residue dissolved in pyridine (1.3 L). A first aliquot of
dimethoxytrityl chloride (94.3 g, 0.278 M) was added and
the mixture stirred at room temperature for one hour. A
second aliquot of dimethoxytrityl chloride (94.3 g, 0.278

10   M) was added and the reaction stirred for an additional one
hour. Methanol (170 mL) was then added to stop the
reaction. HPLC showed the presence of approximately 70%
product. The solvent was evaporated and triturated with
CH_3CN (200 mL). The residue was dissolved in $CHCl_3$ (1.5 L)

15   and extracted with 2x500 mL of saturated $NaHCO_3$ and 2x500 mL
of saturated NaCl. The organic phase was dried over Na_2SO_4,
filtered and evaporated. 275 g of residue was obtained.
The residue was purified on a 3.5 kg silica gel column,
packed and eluted with EtOAc/Hexane/Acetone (5:5:1)

20   containing 0.5% Et_3NH. The pure fractions were evaporated
to give 164 g of product. Approximately 20 g additional
was obtained from the impure fractions to give a total
yield of 183 g (57%).

3'-O-Acetyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-
25 methyluridine:

2'-O-Methoxyethyl-5'-O-dimethoxytrityl-5-methyl-
uridine (106 g, 0.167 M), DMF/pyridine (750 mL of a 3:1
mixture prepared from 562 mL of DMF and 188 mL of pyridine)
and acetic anhydride (24.38 mL, 0.258 M) were combined and

30   stirred at room temperature for 24 hours. The reaction was
monitored by tlc by first quenching the tlc sample with the
addition of MeOH. Upon completion of the reaction, as
judged by tlc, MeOH (50 mL) was added and the mixture

evaporated at 35°C. The residue was dissolved in $CHCl_3$ (800 mL) and extracted with 2x200 mL of saturated sodium bicarbonate and 2x200 mL of saturated NaCl. The water layers were back extracted with 200 mL of $CHCl_3$. The

5 combined organics were dried with sodium sulfate and evaporated to give 122 g of residue (approx. 90% product). The residue was purified on a 3.5 kg silica gel column and eluted using EtOAc/Hexane(4:1). Pure product fractions were evaporated to yield 96 g (84%).

10 3'-O-Acetyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-methyl-4-triazoleuridine:

A first solution was prepared by dissolving 3'-O-acetyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-methyluridine (96 g, 0.144 M) in CH_3CN (700 mL) and set

15 aside. Triethylamine (189 mL, 1.44 M) was added to a solution of triazole (90 g, 1.3 M) in CH_3CN (1 L), cooled to -5?C and stirred for 0.5 h using an overhead stirrer. $POCl_3$ was added dropwise, over a 30 minute period, to the stirred solution maintained at 0-10°C, and the resulting mixture

20 stirred for an additional 2 hours. The first solution was added dropwise, over a 45 minute period, to the later solution. The resulting reaction mixture was stored overnight in a cold room. Salts were filtered from the reaction mixture and the solution was evaporated. The

25 residue was dissolved in EtOAc (1 L) and the insoluble solids were removed by filtration. The filtrate was washed with 1x300 mL of $NaHCO_3$ and 2x300 mL of saturated NaCl, dried over sodium sulfate and evaporated. The residue was triturated with EtOAc to give the title compound.

30 2'-O-Methoxyethyl-5'-O-dimethoxytrityl-5-methylcytidine:

A solution of 3'-O-acetyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-methyl-4-triazoleuridine (103 g, 0.141 M) in dioxane (500 mL) and NH_4OH (30 mL) was stirred at room

temperature for 2 hours. The dioxane solution was
evaporated and the residue azeotroped with MeOH (2x200 mL).
The residue was dissolved in MeOH (300 mL) and transferred
to a 2 liter stainless steel pressure vessel. MeOH (400
5   mL) saturated with NH_3 gas was added and the vessel heated
to 100°C for 2 hours (tlc showed complete conversion). The
vessel contents were evaporated to dryness and the residue
was dissolved in EtOAc (500 mL) and washed once with
saturated NaCl (200 mL). The organics were dried over
10   sodium sulfate and the solvent was evaporated to give 85 g
(95%) of the title compound.

N^4-Benzoyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-methyl-
cytidine:

        2'-O-Methoxyethyl-5'-O-dimethoxytrityl-5-methyl-
15   cytidine (85 g, 0.134 M) was dissolved in DMF (800 mL) and
benzoic anhydride (37.2 g, 0.165 M) was added with
stirring. After stirring for 3 hours, tlc showed the
reaction to be approximately 95% complete. The solvent was
evaporated and the residue azeotroped with MeOH (200 mL).
20   The residue was dissolved in $CHCl_3$ (700 mL) and extracted
with saturated $NaHCO_3$ (2x300 mL) and saturated NaCl (2x300
mL), dried over $MgSO_4$ and evaporated to give a residue (96
g). The residue was chromatographed on a 1.5 kg silica
column using EtOAc/Hexane (1:1) containing 0.5% Et_3NH as the
25   eluting solvent. The pure product fractions were
evaporated to give 90 g (90%) of the title compound.

N^4-Benzoyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-
methylcytidine-3'-amidite:

        N^4-Benzoyl-2'-O-methoxyethyl-5'-O-dimethoxytrityl-5-
30   methylcytidine (74 g, 0.10 M) was dissolved in CH_2Cl_2 (1
L). Tetrazole diisopropylamine (7.1 g) and 2-cyanoethoxy-
tetra(isopropyl)phosphite (40.5 mL, 0.123 M) were added
with stirring, under a nitrogen atmosphere. The resulting

mixture was stirred for 20 hours at room temperature (tlc showed the reaction to be 95% complete). The reaction mixture was extracted with saturated $NaHCO_3$ (1x300 mL) and saturated NaCl (3x300 mL). The aqueous washes were back-

5 extracted with CH_2Cl_2 (300 mL), and the extracts were combined, dried over $MgSO_4$ and concentrated. The residue obtained was chromatographed on a 1.5 kg silica column using EtOAc\Hexane (3:1) as the eluting solvent. The pure fractions were combined to give 90.6 g (87%) of the title

10 compound.

5-methyl-2'-deoxycytidine (5-me-C) containing oligonucleotides were synthesized according to published methods (Sanghvi et al., *Nucl. Acids Res.* **1993**, *21*, 3197-3203) using commercially available phosphoramidites (Glen

15 Research, Sterling VA or ChemGenes, Needham MA).

2=-O-(dimethylaminooxyethyl) nucleoside amidites

2'-(Dimethylaminooxyethoxy) nucleoside amidites [also known in the art as 2'-O-(dimethylaminooxyethyl) nucleoside amidites] are prepared as described in the following

20 paragraphs. Adenosine, cytidine and guanosine nucleoside amidites are prepared similarly to the thymidine (5-methyluridine) except the exocyclic amines are protected with a benzoyl moiety in the case of adenosine and cytidine and with isobutyryl in the case of guanosine.

25 <u>5'-O-tert-Butyldiphenylsilyl-O^2-2'-anhydro-5-methyluridine</u>

O^2-2'-anhydro-5-methyluridine (Pro. Bio. Sint., Varese, Italy, 100.0g, 0.416 mmol), dimethylaminopyridine (0.66g, 0.013eq, 0.0054mmol) were dissolved in dry pyridine (500 ml) at ambient temperature under an argon atmosphere

30 and with mechanical stirring. *tert*-Butyldiphenylchlorosilane (125.8g, 119.0mL, 1.1eq, 0.458mmol) was added in one portion. The reaction was stirred for 16 h at ambient temperature. TLC (Rf 0.22,

ethyl acetate) indicated a complete reaction. The solution
was concentrated under reduced pressure to a thick oil.
This was partitioned between dichloromethane (1 L) and
saturated sodium bicarbonate (2x1 L) and brine (1 L). The
5   organic layer was dried over sodium sulfate and
concentrated under reduced pressure to a thick oil. The
oil was dissolved in a 1:1 mixture of ethyl acetate and
ethyl ether (600mL) and the solution was cooled to -10°C.
The resulting crystalline product was collected by
10 filtration, washed with ethyl ether (3x200 mL) and dried
(40°C, 1mm Hg, 24 h) to 149g (74.8%) of white solid. TLC
and NMR were consistent with pure product.

5'-O-tert-Butyldiphenylsilyl-2'-O-(2-hydroxyethyl)-5-methyluridine

15   In a 2 L stainless steel, unstirred pressure reactor
was added borane in tetrahydrofuran (1.0 M, 2.0 eq, 622
mL). In the fume hood and with manual stirring, ethylene
glycol (350 mL, excess) was added cautiously at first until
the evolution of hydrogen gas subsided. 5'-O-tert-
20 Butyldiphenylsilyl-O^2-2'-anhydro-5-methyluridine (149 g,
0.311 mol) and sodium bicarbonate (0.074 g, 0.003 eq) were
added with manual stirring. The reactor was sealed and
heated in an oil bath until an internal temperature of 160
°C was reached and then maintained for 16 h (pressure < 100
25 psig). The reaction vessel was cooled to ambient and
opened. TLC (Rf 0.67 for desired product and Rf 0.82 for
ara-T side product, ethyl acetate) indicated about 70%
conversion to the product. In order to avoid additional
side product formation, the reaction was stopped,
30 concentrated under reduced pressure (10 to 1mm Hg) in a
warm water bath (40-100°C) with the more extreme conditions
used to remove the ethylene glycol. [Alternatively, once
the low boiling solvent is gone, the remaining solution can
be partitioned between ethyl acetate and water. The

product will be in the organic phase.] The residue was purified by column chromatography (2kg silica gel, ethyl acetate-hexanes gradient 1:1 to 4:1). The appropriate fractions were combined, stripped and dried to product as a

5 white crisp foam (84g, 50%), contaminated starting material (17.4g) and pure reusable starting material 20g. The yield based on starting material less pure recovered starting material was 58%. TLC and NMR were consistent with 99% pure product.

10 2'-O-([2-phthalimidoxy)ethyl]-5'-*t*-butyldiphenylsilyl-5-methyluridine

5'-O-tert-Butyldiphenylsilyl-2'-O-(2-hydroxyethyl)-5-methyluridine (20g, 36.98mmol) was mixed with triphenylphosphine (11.63g, 44.36mmol) and N-

15 hydroxyphthalimide (7.24g, 44.36mmol). It was then dried over P_2O_5 under high vacuum for two days at 40°C. The reaction mixture was flushed with argon and dry THF (369.8mL, Aldrich, sure seal bottle) was added to get a clear solution. Diethyl-azodicarboxylate (6.98mL,

20 44.36mmol) was added dropwise to the reaction mixture. The rate of addition is maintained such that resulting deep red coloration is just discharged before adding the next drop. After the addition was complete, the reaction was stirred for 4 hrs. By that time TLC showed the completion of the

25 reaction (ethylacetate:hexane, 60:40). The solvent was evaporated in vacuum. Residue obtained was placed on a flash column and eluted with ethyl acetate:hexane (60:40), to get 2'-O-([2-phthalimidoxy)ethyl]-5'-*t*-butyldiphenylsilyl-5-methyluridine as white foam (21.819,

30 86%).

5'-O-*tert*-butyldiphenylsilyl-2'-O-[(2-
formadoximinooxy)ethyl]-5-methyluridine

    2'-O-([2-phthalimidoxy)ethyl]-5'-*t*-
butyldiphenylsilyl-5-methyluridine (3.1g, 4.5mmol) was

5 dissolved in dry CH_2Cl_2 (4.5mL) and methylhydrazine (300mL,
4.64mmol) was added dropwise at -10°C to 0°C. After 1 hr
the mixture was filtered, the filtrate was washed with ice
cold CH_2Cl_2 and the combined organic phase was washed with
water, brine and dried over anhydrous Na_2SO_4. The solution

10 was concentrated to get 2'-*O*-(aminooxyethyl) thymidine,
which was then dissolved in MeOH (67.5mL). To this
formaldehyde (20% aqueous solution, w/w, 1.1eg.) was added
and the mixture for 1 hr. Solvent was removed under
vacuum; residue chromatographed to get 5'-O-*tert*-

15 butyldiphenylsilyl-2'-O-[(2-formadoximinooxy) ethyl]-5-
methyluridine as white foam (1.95, 78%).

5'-O-*tert*-Butyldiphenylsilyl-2'-O-[N,N-
dimethylaminooxyethyl]-5-methyluridine

    5'-O-*tert*-butyldiphenylsilyl-2'-O-[(2-

20 formadoximinooxy)ethyl]-5-methyluridine (1.77g, 3.12mmol)
was dissolved in a solution of 1M pyridinium p-
toluenesulfonate (PPTS) in dry MeOH (30.6mL). Sodium
cyanoborohydride (0.39g, 6.13mmol) was added to this
solution at 10°C under inert atmosphere. The reaction

25 mixture was stirred for 10 minutes at 10°C. After that the
reaction vessel was removed from the ice bath and stirred
at room temperature for 2 hr, the reaction monitored by TLC
(5% MeOH in CH_2Cl_2). Aqueous $NaHCO_3$ solution (5%, 10mL) was
added and extracted with ethyl acetate (2x20mL). Ethyl

30 acetate phase was dried over anhydrous Na_2SO_4, evaporated to
dryness. Residue was dissolved in a solution of 1M PPTS in
MeOH (30.6mL). Formaldehyde (20% w/w, 30mL, 3.37mmol) was
added and the reaction mixture was stirred at room

temperature for 10 minutes. Reaction mixture cooled to 10°C in an ice bath, sodium cyanoborohydride (0.39g, 6.13mmol) was added and reaction mixture stirred at 10°C for 10 minutes. After 10 minutes, the reaction mixture was

5   removed from the ice bath and stirred at room temperature for 2 hrs. To the reaction mixture 5% $NaHCO_3$ (25mL) solution was added and extracted with ethyl acetate (2x25mL). Ethyl acetate layer was dried over anhydrous Na_2SO_4 and evaporated to dryness . The residue obtained was

10   purified by flash column chromatography and eluted with 5% MeOH in CH_2Cl_2 to get 5'-O-*tert*-butyldiphenylsilyl-2'-O-[N,N-dimethylaminooxyethyl]-5-methyluridine as a white foam (14.6g, 80%).

2'-O-(dimethylaminooxyethyl)-5-methyluridine

15   Triethylamine trihydrofluoride (3.91mL, 24.0mmol) was dissolved in dry THF and triethylamine (1.67mL, 12mmol, dry, kept over KOH). This mixture of triethylamine-2HF was then added to 5'-O-*tert*-butyldiphenylsilyl-2'-O-[N,N-dimethylaminooxyethyl]-5-methyluridine (1.40g, 2.4mmol) and

20   stirred at room temperature for 24 hrs. Reaction was monitored by TLC (5% MeOH in CH_2Cl_2). Solvent was removed under vacuum and the residue placed on a flash column and eluted with 10% MeOH in CH_2Cl_2 to get 2'-O-(dimethylaminooxyethyl)-5-methyluridine (766mg, 92.5%).

5'-O-DMT-2'-O-(dimethylaminooxyethyl)-5-methyluridine

25   2'-O-(dimethylaminooxyethyl)-5-methyluridine (750mg, 2.17mmol) was dried over P_2O_5 under high vacuum overnight at 40°C. It was then co-evaporated with anhydrous pyridine (20mL). The residue obtained was dissolved in pyridine

30   (11mL) under argon atmosphere. 4-dimethylaminopyridine (26.5mg, 2.60mmol), 4,4'-dimethoxytrityl chloride (880mg, 2.60mmol) was added to the mixture and the reaction mixture was stirred at room temperature until all of the starting

material disappeared. Pyridine was removed under vacuum
and the residue chromatographed and eluted with 10% MeOH in
CH_2Cl_2 (containing a few drops of pyridine) to get 5'-O-DMT-
2'-O-(dimethylamino-oxyethyl)-5-methyluridine (1.13g, 80%).

5 5'-O-DMT-2'-O-(2-N,N-dimethylaminooxyethyl)-5-
   methyluridine-3'-[(2-cyanoethyl)-N,N-
   diisopropylphosphoramidite]

        5'-O-DMT-2'-O-(dimethylaminooxyethyl)-5-methyluridine
   (1.08g, 1.67mmol) was co-evaporated with toluene (20mL).
10 To the residue N,N-diisopropylamine tetrazonide (0.29g,
   1.67mmol) was added and dried over P_2O_5 under high vacuum
   overnight at 40°C. Then the reaction mixture was dissolved
   in anhydrous acetonitrile (8.4mL) and 2-cyanoethyl-
   N,N,N^1,N^1-tetraisopropylphosphoramidite (2.12mL, 6.08mmol)
15 was added. The reaction mixture was stirred at ambient
   temperature for 4 hrs under inert atmosphere. The progress
   of the reaction was monitored by TLC (hexane:ethyl acetate
   1:1). The solvent was evaporated, then the residue was
   dissolved in ethyl acetate (70mL) and washed with 5%
20 aqueous $NaHCO_3$ (40mL). Ethyl acetate layer was dried over
   anhydrous Na_2SO_4 and concentrated. Residue obtained was
   chromatographed (ethyl acetate as eluent) to get 5'-O-DMT-
   2'-O-(2-N,N-dimethylaminooxyethyl)-5-methyluridine-3'-[(2-
   cyanoethyl)-N,N-diisopropylphosphoramidite] as a foam
25 (1.04g, 74.9%).

        Oligonucleotides having methylene(methylimino) (MMI)
   backbones are synthesized according to U.S. patent
   5,378,825, which is coassigned to the assignee of the
   present invention and is incorporated herein in its
30 entirety. For ease of synthesis, various nucleoside dimers
   containing MMI linkages are synthesized and incorporated
   into oligonucleotides. Other nitrogen-containing backbones
   are synthesized according to WO 92/20823 which is also

coassigned to the assignee of the present invention and
incorporated herein in its entirety.

Oligonucleotides having amide backbones are
synthesized according to De Mesmaeker *et al.* (*Acc. Chem.*
5 *Res.* **1995***, 28,* 366-374). The amide moiety is readily
accessible by simple and well-known synthetic methods and
is compatible with the conditions required for solid phase
synthesis of oligonucleotides.

Oligonucleotides with morpholino backbones are
10 synthesized according to U.S. patent 5,034,506 (Summerton
and Weller).

Peptide-nucleic acid (PNA) oligomers are synthesized
according to P.E. Nielsen *et al.* (*Science* **1991***, 254,* 1497-
1500).

15   After cleavage from the controlled pore glass column
(Applied Biosystems) and deblocking in concentrated
ammonium hydroxide at 55°C for 18 hours, the
oligonucleotides are purified by precipitation twice out of
0.5 M NaCl with 2.5 volumes ethanol. Synthesized
20 oligonucleotides were analyzed by polyacrylamide gel
electrophoresis on denaturing gels or capillary gel
electrophoresis and judged to be at least 85% full length
material. The relative amounts of phosphorothioate and
phosphodiester linkages obtained in synthesis were
25 periodically checked by ^{31}P nuclear magnetic resonance
spectroscopy, and for some studies oligonucleotides were
purified by HPLC, as described by Chiang *et al.* (*J. Biol.*
Chem. **1991***, 266,* 18162). Results obtained with HPLC-
purified material were similar to those obtained with non-
30 HPLC purified material.

Alternatively, oligonucleotides are synthesized in 96
well plate format via solid phase P(III) phosphoramidite
chemistry on an automated synthesizer capable of assembling
96 sequences simultaneously in a standard 96 well format.

Phosphodiester internucleotide linkages are afforded by oxidation with aqueous iodine. Phosphorothioate internucleotide linkages are generated by sulfurization utilizing 3,H-1,2 benzodithiole-3-one 1,1 dioxide (Beaucage

5   Reagent) in anhydrous acetonitrile. Standard base-protected beta-cyanoethyl-di-isopropyl phosphoramidites are purchased from commercial vendors (e.g. PE-Applied Biosystems, Foster City, CA, or Pharmacia, Piscataway, NJ). Non-standard nucleosides are synthesized

10 as per published methods. They are utilized as base protected beta-cyanoethyldiisopropyl phosphoramidites.

Oligonucleotides were cleaved from support and deprotected with concentrated NH_4OH at elevated temperature (55-60°C) for 12-16 hours and the released product then

15 dried in vacuo. The dried product was then re-suspended in sterile water to afford a master plate from which all analytical and test plate samples are then diluted utilizing robotic pipettors.

EXAMPLE 2: Human FAK Oligonucleotide Sequences

20   Antisense oligonucleotides were designed to target human FAK. Target sequence data are from the focal adhesion kinase (FAK) cDNA sequence published by Whitney, G.S., *et al.* (*DNA Cell Biol.*, **1993**, *12*, 823-830); Genbank accession number L13616, provided herein as SEQ ID NO: 1.

25 One set of oligonucleotides were synthesized as chimeric oligonucleotides ("gapmers"), 20 nucleotides in length, composed of a central "gap" region consisting of ten 2'-deoxynucleotides, which is flanked on both sides (5' and 3' directions) by five-nucleotide "wings." The wings are

30 composed of 2'-methoxyethyl (2'-MOE) nucleotides. The internucleoside (backbone) linkages are phosphorothioate (P=S) throughout the oligonucleotide. All 2'-MOE cytosines were 5-methyl-cytosines. These oligonucleotide sequences are shown in Table 1. An identical set of sequences were

prepared as fully phosphorothioated oligodeoxynucleotides.
These are shown in Table 2. An additional set of
oligonucleotides were synthesized as chimeric
oligonucleotides ("gapmers"), 15 nucleotides in length,

5 composed of a central "gap" region consisting of five
2'-deoxynucleotides, which is flanked on both sides (5' and
3' directions) by five-nucleotide "wings." The wings are
composed of 2'-methoxyethyl (2'-MOE) nucleotides. The
internucleoside (backbone) linkages are phosphorothioate

10 (P=S) throughout the oligonucleotide. All 2'-MOE cytosines
were 5-methyl-cytosines. These oligonucleotide sequences
are shown in Table 3. An identical set of sequences were
prepared as fully phosphorothioated oligodeoxynucleotides.
These are shown in Table 4.

15   Human A549 lung carcinoma cells (American Type
Culture Collection, Manassas, VA) were grown in DMEM
supplemented with 10% fetal bovine serum (FBS), non-
essential amino acids for MEM, sodium pyruvate (1 mM),
penicillin (50 U/ml) and streptomycin (50 μg/ml). All cell

20 culture reagents were obtained from Life Technologies
(Rockville, MD).

         The cells were washed once with OPTIMEM™ (Life
Technologies, Rockville, MD), then transfected with 400 nM
oligonucleotide and 12 mg/ml LIPOFECTIN^R (Life Technologies,

25 Rockville, MD), a 1:1 (w/w) liposome formulation of the
cationic lipid N-[1-(2,3-dioleyloxy)propyl]-n,n,n-
trimethylammonium chloride (DOTMA), and dioleoyl
phosphotidylethanolamine (DOPE) in membrane filtered water.
The cells were incubated with oligonucleotide for four

30 hours, after which the media was replaced with fresh media
and the cells incubated for another 20 hours.

         Total cellular RNA was isolated using an ATLAS™ Pure
RNA isolation kit (Clontech, Palo Alto, CA). RNA was then
separated on a 1.2% agarose-formaldehyde gel, transferred

35 to Hybond-N+ membrane (Amersham Pharmacia Biotech,

Arlington Heights, IL), a positively charged nylon
membrane. Immobilized RNA was cross-linked by exposure to
UV light. Membranes were probed with either FAK or
glyceraldehyde 3-phosphate dehydrogenase (G3PDH) probes.

5 The probes were labeled by random primer using the PRIME-A-
GENE[7] Labeling System, Promega, Madison, WI) and hybridized
to the membranes. mRNA signals were quantitated by a
PhosphoImager (Molecular Dynamics, Sunnyvale, CA).

        Results of an initial screen of the FAK antisense
10 oligonucleotides are shown in Tables 5 (20 mers) and 6 (15
mers). Oligonucleotides 15392 (SEQ ID NO. 3), 15394 (SEQ
ID NO. 4), 15397 (SEQ ID NO. 6), 15399 (SEQ ID NO. 7),
15401 (SEQ ID NO. 8), 15403 (SEQ ID NO. 9), 15405 (SEQ ID
NO. 10), 15407 (SEQ ID NO. 11), 15409 (SEQ ID NO. 12),
15 15413 (SEQ ID NO. 14), 15415 (SEQ ID NO. 15), 15458 (SEQ ID
NO. 16), 15460 (SEQ ID NO. 17), 15421 (SEQ ID NO. 18),
15425 (SEQ ID NO. 20), 15393 (SEQ ID NO. 23), 15406 (SEQ ID
NO. 30), 15408 (SEQ ID NO. 31) and 15412 (SEQ ID NO. 33)
resulted in about 50% or greater inhibition of FAK mRNA
20 expression in this assay. Oligonucleotides 15401 (SEQ ID
NO. 8), 15403 (SEQ ID NO. 9), 15409 (SEQ ID NO. 12), 15413
(SEQ ID NO. 14), 15415 (SEQ ID NO. 15), and 15421 (SEQ ID
NO. 18) resulted in about 80% or greater inhibition of FAK
mRNA expression.

EXAMPLE 3: Dose response of antisense phosphorothioate oligonucleotide effects on FAK levels in A549 cells

Several of the more active oligonucleotides were chosen for a dose response study. A549 cells were grown, treated and processed as described in Example 2, except the concentration of oligonucleotide was varied.

Results are shown in Table 7. Many oligonucleotides showed IC_{50}s of 50 nM or less and maximal inhibition seen was 95%.

    A dose response experiment on protein levels was done with two oligonucleotides. A549 cells were grown and treated as described in Example 2 except the concentration was varied as shown in Table 3. The LIPOFECTIN[R] to oligonucleotide ratio was maintained at 3 mg/ml LIPOFECTIN[R] per 100 nM oligonucleotide. FAK protein levels were determined 48 hours after antisense treatment in whole cell

lysates by anti-FAK blotting. Cells on 10cm plates were

lysed with 0.5 ml modified RIPA lysis buffer, diluted with

0.5 ml HNTG buffer (50 mM HEPES, pH 7.4, 150 mM NaCl, 0.1%

Triton X-100, 10% glycerol), incubated with agarose beads,

5   and cleared by centrifugation. Immunoprecipitations with a

polyclonal FAK antibody (Salk Institute of Biological

Studies, La Jolla, CA; additional FAK antibodies available

from Upstate Biotechnology Incorporated, Lake Placid, NY)

were performed for 4hr at 4°C, collected on protein A

10   (Repligen, Cambridge, MA) or protein G-plus (Calbiochem)

agarose beads, and the precipitated protein complexes were

washed at 4°C in Triton only lysis buffer (modified RIPA

without sodium deoxycholate and SDS) followed by washing in

HNTG buffer prior to direct analysis by SDS-PAGE. For

15   immunoblotting, proteins were transferred to polyvinylidene

fluoride membranes (Millipore) and incubated with a 1:1000

dilution of polyclonal antibody for 2 hr at room

temperature. Bound primary antibody was visualized by

enhanced chemiluminescent detection.

20   Results are shown in Table 8.

EXAMPLE 4: Effect of FAK antisense phosphorothioate oligonucleotides on growth factor stimulated migration and invasion

Integrin-regulated focal adhesion kinase (FAK) is an important component of epidermal (EGF) and platelet-drived (PDGF) growth factor-induced motility of primary fibroblasts, smooth muscle, and adenocarcinoma cells. To measure the effect of FAK antisense oligonucleotides on cell migration, a modified Boyden chamber (Millipore, Bedford, MA) assay was used (Sieg, D.J., *et al., J. Cell Sci.,* **1999**, *112*, 2677-2691). Both membrane sides were coated with rat tail collagen (5 ?g/ml in PBS, Boehringer Mannheim) for 2 hr at 37°C, washed with PBS, and the chambers were placed into 24 well dishes containing migration media (0.5 ml DMEM containing 0.5% BSA) with or without human recombinant PDGF-BB, EGF, or basic-FGF (Calbiochem, San Diego, CA) at the indicated concentrations. Serum-starved A549 cells (1×10^5 cells in 0.3 ml migration media) were added to the upper chamber and after 3 hr at 37°C, the cells on the membrane upper surface were removed by a cotton tip applicator, the migratory cells on the lower membrane surface were fixed, stained (0.1% crystal violet, 0.1 M borate pH 9.0, 2% EtOH), and the dye eluted for absorbance measurements at 600 nM. Individual experiments represent the average from three individual chambers. Background levels of cell migration (less than 5% of total) in the absence of chemotaxis stimuli (0.5% BSA only) were subtracted from all points.

Results are shown in Table 9. ISIS 17636 (SEQ ID NO. 43) is a five base mismatch control oligonucleotide for ISIS 15421 (SEQ ID NO. 18).

TABLE 9

Effect of FAK Antisense Phosphorothioate Oligonucleotides on EGF-Stimulated Cell Migration

ISIS #	SEQ ID NO:	ASO Gene Target	EGF (ng/ml)	A_{600}
control	---	---	2.5	0.74
15421	18	3'-UTR	"	0.26
17636	43	control	"	0.90
control	---	---	5.0	0.89
15421	18	3'-UTR	"	0.25
17636	43	control	"	0.77

FAK antisense oligonucleotides were tested in an *in vitro* invasion assay using an ~1mm MATRIGEL[R] (Becton Dickinson, Franklin Lakes, NJ) basement membrane barrier (Albini, A., *Pathol. Oncol. Res.*, **1998**, *4*, 230-241). Migration chambers were coated with the indicated concentration of MATRIGEL[R], dried under laminar flow and then rehydrated with cold serum free DMEM for 90 min on an orbital shaker. A549 cells were grown and transfected as described in Example 2. Cells (1×10^5) were then placed onto the MATRIGEL[R] coated membrane and allowed to invade through the MATRIGEL[R] towards a 10% FBS chemoattractant for the indicated times. Cells that invaded through the MATRIGEL[R] were visualized by crystal violet staining as detailed in the migration assay. The amount of MATRIGEL[R] was varied in the assay to show that invasion was being measured and that the migration was not serum-induced.

Results are shown in Table 10.

TABLE 10

Effect of FAK Antisense Phosphorothioate Oligonucleotides on Tumor Cell Invasion

EXAMPLE 5: **FAK antisense oligonucleotides in a retinal neovascularization model**

FAK antisense oligonucleotides were tested in a rabbit model of retinal neovascularization (Kimura, H., *et al.*, *Invest. Opthalmol. Vis. Sci.*, **1995**, *36*, 2110-2119). In this model, growth factors are encapsulated and injected beneath the retina.

Eight male Dutch Belt rabbits and one male Black Satin/New Zealand White Cross rabbit were used in this study. ISIS 15409 (SEQ ID NO. 12) was administered intravitreally by injection, once prior to surgical implantation of the polymeric pellets and once during pellet implantation. Retinal neovascularization was monitored by indirect opthalmolscopy and documented by fundus photography. Retinal neovascularization was graded on a scale from 1 to 5, with one being normal and five showing retinal hemorrhaging and/or detachment. In animals injected with saline and the growth factor containing pellets, evidence of retinal neovascularization could be

detected in the first week and retinal hemorrhaging began by the end of the third week. Animals receiving the antisense FAK oligonucleotide showed no evidence of retinal neovascularization over a four week period.

5 **EXAMPLE 6: Effect of FAK antisense phosphorothioate oligonucleotide (ISIS 15421) alone and in combination with 5-Flurouracil on the viability of melanoma cell lines**

Inhibition of FAK in tumor cell lines causes cell rounding, loss of adhesion, and apoptosis which suggests a

10 role for these inhibitors in the treatment of metastatic conditions. In these studies, an antisense inhibitor of FAK was tested alone and in combination with the chemotherapeutic agent, 5-FU for its effects on melanoma cell line viability.

15 C8161 and BL human melanoma cell lines were treated with ISIS 15421 (SEQ. ID. NO 18) or a control oligonucleotide, ISIS 29848, a 20-mer random oligonucleotide (NNNNNNNNNNNNNNNNNNNN, wherein each N is a mixture of A, C, G and T; herein incorporated as SEQ ID NO: 44) using the

20 lipofectin protocol described herein. Oligonucleotides were transfected for four hours at 300 nM in lipofectin reagent and 5-FU (200 µg/mL; SIGMA) was added after the incubation for 20 hours. Cell viability was determined by the MTT assay. Loss of adhesion and apoptosis were

25 determined by cell counting and the TUNEL assay, respectively. FAK expression was assayed by Western blot, probing with the anti-FAK clone 4.47 antibody (Upstate Biotechnology, Lake Placid, NY).

In The BL melanoma cell line, treatment with ISIS

30 15421 resulted in a 23% reduction in cell viability compared to control (p<0.0001). Addition of 5-FU to the antisense treated cells resulted in a significant further reduction in cell viability (69%; p<0.0001) compared to treatment with ISIS 15421 or 5-FU alone (4.4% reduction;

p=0.15) or the control oligonucleotide, ISIS 29848.
Similar results were seen with the C8161 cell line.

In both cell lines, reduction in cell viability was
accompanied by a proportional loss of cell adhesion and an
5 increase in apoptosis. Western blots showed that treatment
with ISIS 15421 resulted in a decrease of FAK protein
expression. FAK protein levels were decreased in BL
melanoma cells upon treatment with 5-FU alone and were
undetectable upon treatment with the combination of ISIS
10 15421 and 5-FU. These studies suggest that ISIS 15421, in
combination with the chemotherapeutic agent 5-FU, may be a
useful in the treatment of melanoma.

**EXAMPLE 7: Effect of FAK antisense phosphorothioate
oligonucleotide (ISIS 15421) on human melanoma xenograft
15 tumor growth in mice**

Another model used to investigate the efficacy of
antisense oligonucleotides on tumor growth involves the use
of mice transplanted with human cancer cells or cell line
tumors. In these experiments human C8161 melanoma tumor
20 xenografts were transplanted onto the side of nude mice
with sutures or surgical staples. Mice were treated with
ISIS 15421 (SEQ ID NO. 18) or the control ISIS 29848 (SEQ
ID NO. 44) over a 28 day treatment course.

At the end of the timecourse, mice were sacrificed
25 and tumor volumes measured. Tumor volumes in the
antisense treated mice were significantly smaller than
tumor volumes in control-treated mice with no observation
of toxicity to the mice. Additionally, one third of the
control-treated mice had grossly evident intraperitoneal
30 metastases, while none of the antisense-treated mice
displayed such metastases. These studies suggest that
antisense oligonucleotides represent potential
chemotherapeutic agents in the treatment of melanoma and
the prevention of tumor metastasis.
